SMD - QUIZ 4

OTP Phone Number Verification

React Native / Expo - Screenshots of the complete flow

A mobile application that verifies a phone number with a one-time passcode delivered by SMS. The user enters their number, the server asks the SMS provider to send a 6-digit code, the user types that code, and the app reports success or failure.

Repository	https://github.com/HussnainShah72/otp-phone-verification
App	React Native 0.88 / Expo SDK 58, TypeScript
Backend	Node.js + Express, Twilio Verify v2 integration
Running as	Demo provider (see note below)

A note on the SMS provider

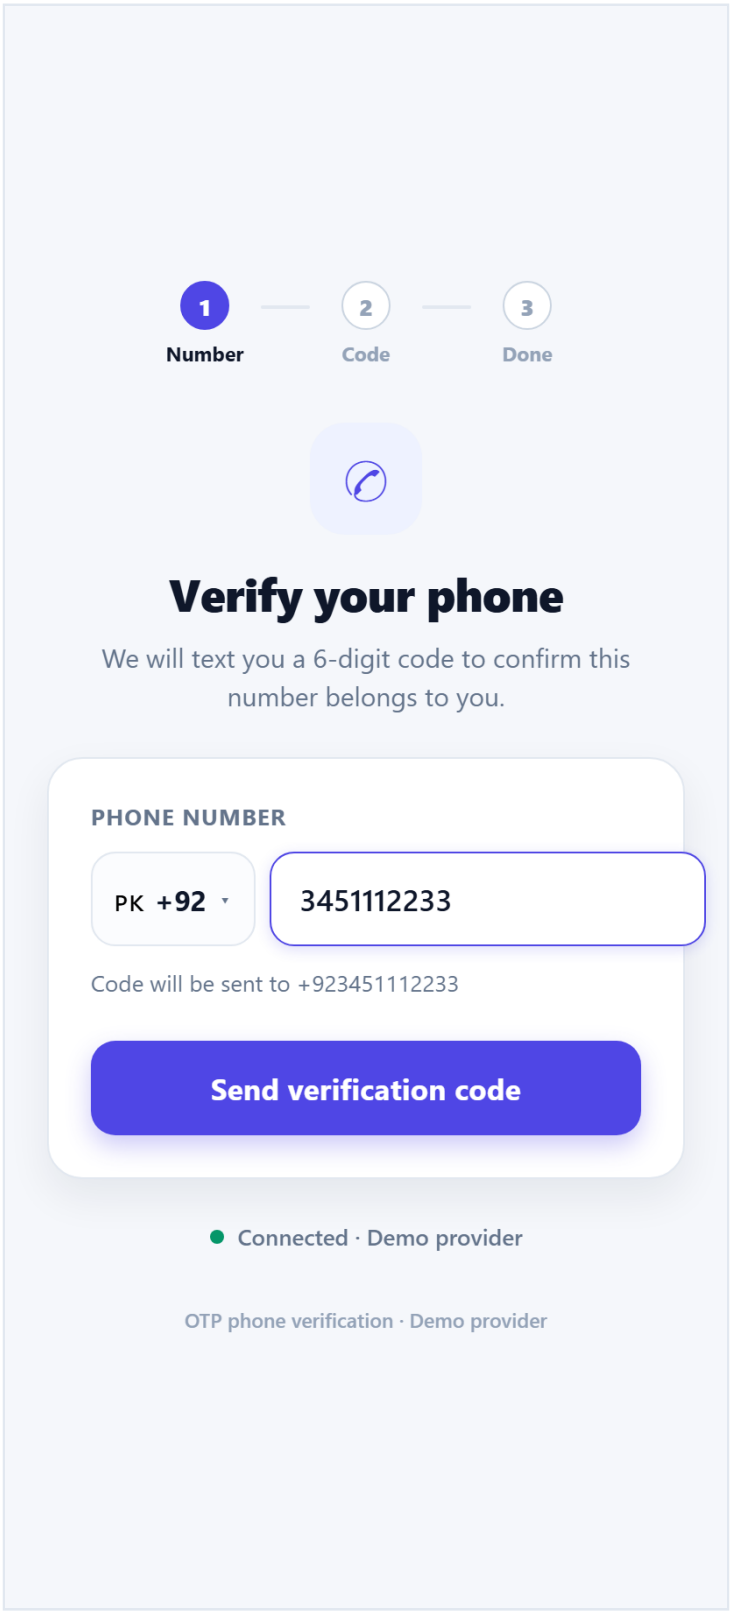

Twilio does not offer free trials in Pakistan - the console reports “Trials are currently unavailable in your region” with zero free SMS. Firebase Phone Auth is not an alternative either: SMS sign-in was removed from the free Spark plan in September 2024 and now requires a billing-enabled Blaze plan. Pakistan also requires PTA-approved sender IDs for A2P messaging, which is why trial routes are blocked.

The Twilio Verify integration in the repository is complete and activates as soon as credentials are supplied, with no code changes. For these captures the server runs its demo provider, which generates a real 6-digit code with the same expiry, single-use rule and 5-attempt limit, but prints it on screen instead of sending an SMS. That is why the code is visible in the screenshots that follow.

STEP 1

Enter phone number

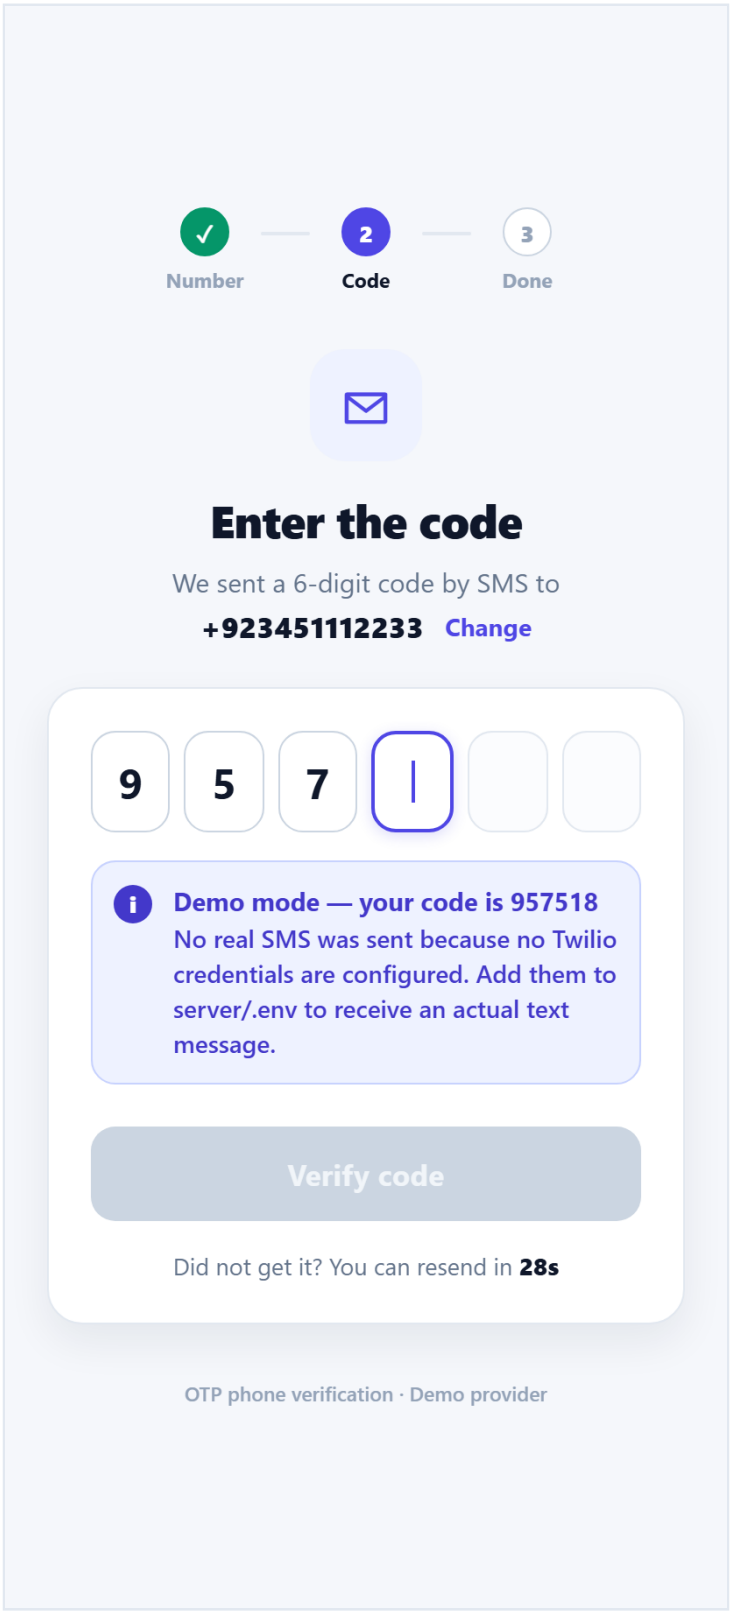

The user picks a country code and types their number. The app normalises it to E.164 and previews the exact number the code will be sent to. The footer confirms the verification server is reachable and names the active provider.

STEP 2

Request and receive the OTP

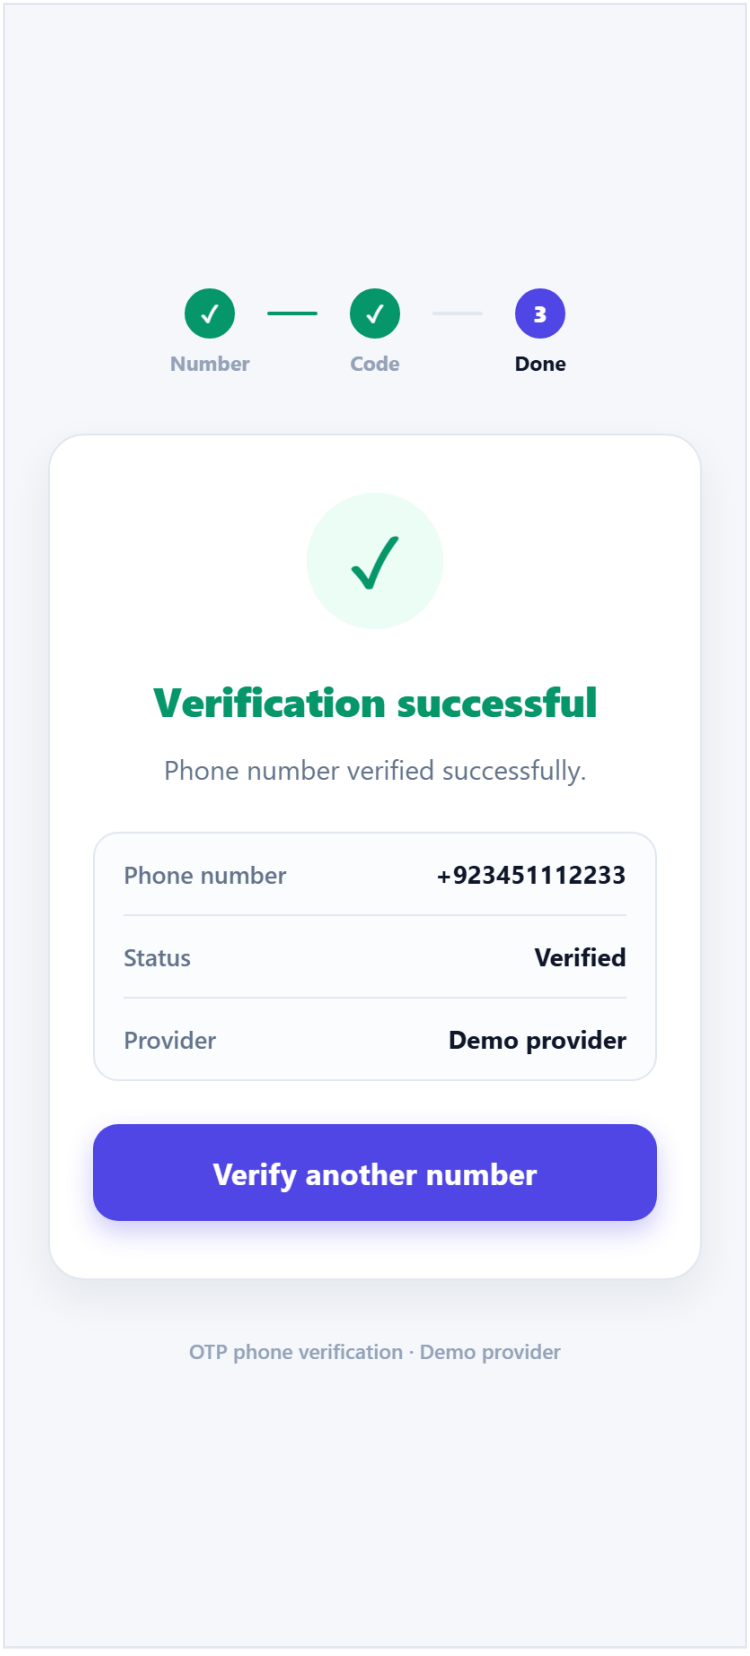

The server has issued a 6-digit code and the app is on the code screen. Digits are entered into six boxes backed by a single hidden input, so paste and SMS autofill work. A 30-second resend cooldown counts down beneath the button.

STEP 3

Verification successful

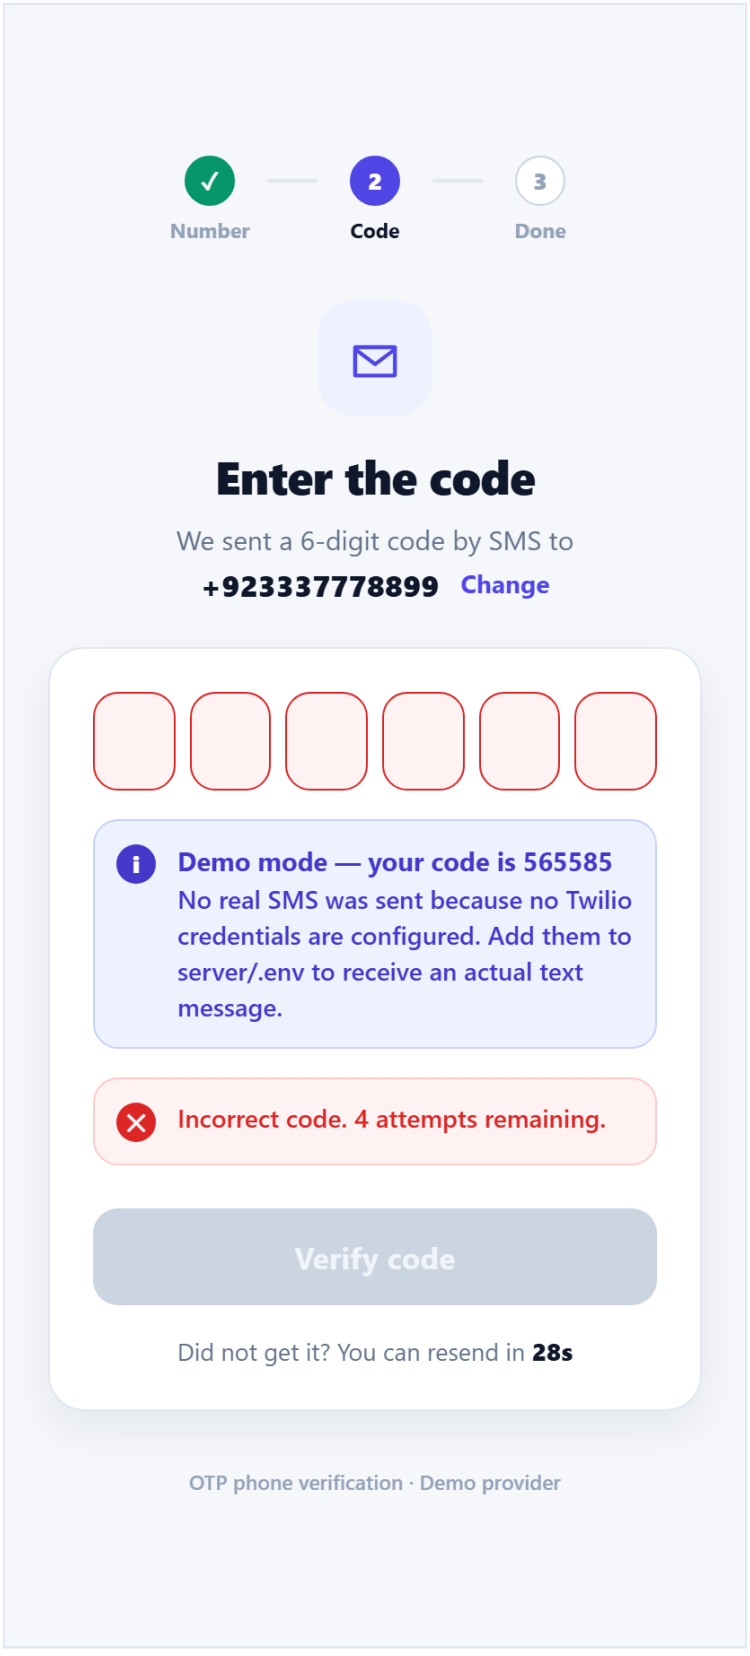

The correct code was accepted. The app shows an explicit success message with the verified number, the status and the provider that performed the check.

ERROR HANDLING

Incorrect code, retry allowed

A wrong code is a normal outcome, not a crash. The boxes turn red and the remaining attempt count is shown, letting the user try again without leaving the screen.

STEP 3 (ALTERNATE)

Verification failed

Once the attempt limit is exhausted the code is invalidated and the app shows an explicit failure message, offering a fresh code or a different number.
